

Aggregation Switches Type 1 and Type 2

Overview

What Is an Aggregation Switch and How to Choose?

Discover the role of aggregation switches. Explore differences between aggregation, access, and core switch.

Key Takeaways

Aggregation switches consolidate traffic from multiple access switches and forward it to core switches, with Type 1 and Type 2 differing mainly in performance, port density, and deployment scenarios.

Overview of Aggregation Switches

An aggregation switch serves as an intermediary between access layer switches and core switches, consolidating traffic from multiple devices such as PCs, IP phones, and wireless access points, and forwarding it efficiently to the network core. They operate at Layer 2 or Layer 3, support link aggregation protocols like LACP, and provide redundancy, high throughput, and QoS management. Aggregation switches are essential in enterprise backbones, campus networks, and data centers, ensuring scalable and reliable network performance.

Type 1 Aggregation Switches Type 1 switches are typically deployed in campus or enterprise aggregation layers. Key characteristics include: Medium to high port density to connect multiple access switches. Layer 2 and some Layer 3 functionality, including VLAN support, inter-VLAN routing, and basic routing protocols.

Qo

S and traffic prioritization, allowing special traffic like VoIP or video conferencing to be prioritized. Stacking capability for device-level backup and increased interface density. Suitable for wired and wireless convergence, acting as a gateway for both types of traffic.

Type 1 switches are optimized for campus networks, where multiple access switches need to be aggregated efficiently while maintaining moderate routing and security features. Type 2 Aggregation Switches Type 2 switches are generally used in data center aggregation layers or high-performance enterprise networks. Key features include: High port density and high throughput, often supporting 10/25/40/100 Gbps uplinks.

Advanced Layer 3 capabilities, including full routing, virtual device contexts (VDCs), and control-plane isolation for multi-tenant environments.

Support for Virtual Port

Channel (vPC) and link aggregation to enhance redundancy and load balancing. Segmentation and security at both data and control planes, suitable for multi-tenant or high-traffic environments. Designed for data center aggregation, connecting access switches to core switches while handling massive traffic volumes efficiently.

Key Differences Between Type 1 and Type 2

Feature	Type 1	Type 2
Deployment	Campus networks	Data centers / high-performance networks
Port density	High	Medium to high
Layer support	L2 + some L3	Full L2/L3 with advanced routing
Traffic handling	QoS, VLAN, basic routing	High throughput, vPC, multi-tenant isolation
Redundancy	Stacking, link aggregation	vPC, link aggregation, control-plane isolation
Use case	Aggregating access switches in enterprise	Aggregating access switches in data centers with high traffic

Conclusion Type 1 aggregation switches are ideal for campus networks requiring moderate routing, QoS, and traffic management, while Type 2 switches are designed for high-performance data center environments with advanced Layer 3 features, high port density, and multi-tenant support.

Both types play a critical role in efficiently consolidating access layer traffic and ensuring reliable connectivity to the core network.
