

How can a splitter network be used

Product Wiring Diagram

Overview

Instead of running a second cable, you can use a splitter on both ends. One splitter takes the two signals and merges them into one cable.

Key Takeaways

Splitter networks allow a single network connection to serve multiple devices by dividing the signal, either over Ethernet cables or optical fibers, without requiring additional cabling.

Ethernet Splitter Networks

Ethernet splitters are used to share a single Ethernet cable between two devices in situations where running additional cables is impractical, such as in homes or offices with limited wall ports or router connections. They work by repurposing unused wire pairs in standard Ethernet cables (Cat5e or Cat6) to carry separate signals. For example, older 10/100 Mbps Ethernet only uses two of the four twisted pairs, allowing a splitter to allocate the remaining pairs to a second device.

Key points for Ethernet splitters: Two splitters are required: one at the source and one at the destination to separate the signals. Bandwidth is shared: splitters do not increase total network speed; each device may experience reduced performance if both are active simultaneously. Compatibility: they are generally limited to 10/100 Mbps networks and are not suitable for Gigabit Ethernet, which uses all four pairs.

Ethernet splitters are ideal for temporary setups, low-bandwidth environments, or space-constrained installations where adding new cables is difficult or costly.

Optical Splitter Networks

In fiber-optic networks, optical splitters are used in Passive Optical Networks (PONs) to divide a single optical signal from a central Optical Line Terminal (OLT) into multiple outputs for Optical Network Terminals (ONTs) at subscribers' homes. This allows one fiber to serve multiple users, reducing infrastructure costs and simplifying network expansion. Key features of optical splitters: Passive operation: no power is required, lowering operational costs.

Scalability: a single OLT port can serve 8-64 ONTs depending on the splitter ratio, making it easy to add new subscribers. Types: Fused Biconical Taper (FBT) splitters are cost-effective for small splits, while Planar Lightwave Circuit (PLC) splitters provide uniform performance for large splits like 1: 32 or 1: 64. Optical splitters are widely used in Fiber-to-the-Home (FTTH) deployments, enabling efficient, cost-effective broadband delivery without requiring dedicated fibers for each subscriber.

Summary

Splitter networks are a practical solution for expanding connectivity without additional cabling. Ethernet splitters are suitable for short-distance, low-speed applications, while optical splitters are essential in fiber networks for serving multiple users efficiently. Both types require careful consideration of bandwidth limitations and network compatibility to ensure reliable performance.
