

Optical Power Meter Measurement and Transmission

Overview

An increasingly common special-purpose OPM, commonly called a "PON Power Meter" is designed to hook into a live PON (Passive Optical Network) circuit, and simultaneously test the optical power in different directions and wavelengths. This unit is essentially a triple power meter, with a collection of wavelength filters and optical couplers. Proper calibration is complicated by the varying duty cycle of the measured optical signals.

Key Takeaways

An optical power meter measures the power of light transmitted through a fiber, allowing evaluation of optical link performance and transmission loss. Overview of Optical Power Meters

An optical power meter (OPM) is an electronic test device used to measure the power of an optical signal, typically in fiber optic systems. It consists of a photodiode sensor, a measuring amplifier, and a display that shows the optical power and the selected wavelength. The sensor converts incoming light into an electrical current proportional to the optical power, enabling accurate measurement of average power levels. OPMs can be handheld, bench-top, or integrated into larger test systems such as OTDRs or optical loss test sets (OLTS), .

Measuring Transmission with an Optical Power Meter

To assess optical transmission, an OPM is often used in combination with a light source. The procedure involves:

- Connecting the light source to one end of the fiber link.
- Setting the OPM to the same wavelength as the light source, matching the service transmission wavelength (commonly 850nm, 1300nm for multimode fiber, and 1310nm, 1550nm for single-mode fiber), .
- Measuring the power at the far end of the fiber.
- Comparing the measured power with the reference power obtained by connecting the light source directly to the OPM without the fiber link. The difference between these readings represents the net optical loss or insertion loss of the fiber link, expressed in decibels (dB) . This method allows technicians to evaluate the transmission efficiency and detect issues such as high attenuation, connector losses, or fiber defects.

Advanced Applications

- Optical Loss Test Sets (OLTS): Combine a light source and one or more power meters to measure end-to-end loss and optical return loss in fiber networks .
- OTDR Integration: While OPMs measure absolute power, OTDRs can provide a distance-resolved loss profile, identifying faults, splices, or breaks along the fiber .
- Data Transmission Monitoring: Some modern OPMs can transmit measurement data to computers via USB, Ethernet, or GPIB, enabling automated monitoring of multiple fibers or ports .

Key Considerations

- Wavelength Calibration: OPMs are wavelength-dependent, so the meter must be set to the correct test wavelength to avoid inaccurate readings .
- Sensor Type: Common sensors include Silicon (Si), Germanium (Ge), and Indium Gallium Arsenide (InGaAs), chosen based on the wavelength range and power levels .
- Measurement Units: Power is typically displayed in dBm or mW, while loss is expressed in dB, a dimensionless ratio of measured to reference power . In summary, optical power meters are essential tools for measuring the transmission of optical signals, determining insertion loss, and ensuring fiber optic networks meet performance specifications. They are widely used in installation, maintenance, and certification of fiber links .
